Brain-Computer Interfaces

- Brain-Computer Interface (BCI)
- Direct communication between brain and machine
- Bypasses innate motor-based means of communication
- Control a computerized device using only thoughts
- Voluntary changes in mental state, not mind reading!
- Uses patterns associated with mental cues

Uses for BCI

- BCI have many potential uses
- Reestablish communication with people who are Locked-in
 - Aware and cognitive function but unable to communicate
 - ALS, stroke, traumatic brain injury
- Assistive technology
 - electric wheelchairs, computers, telephones
- Everyday devices
 - video games, monitoring emotional states

Electroencephalography

- Electroencephalography (EEG) to measure brain activity
- Non-invasive, portable, relatively inexpensive
- Superficial & noisy signals

- Machine Learning algorithms identify patterns in EEG
- This is **extremely** difficult because
 - different for each person
 - change over time
 - noise & artifacts
 - the brain is complex!

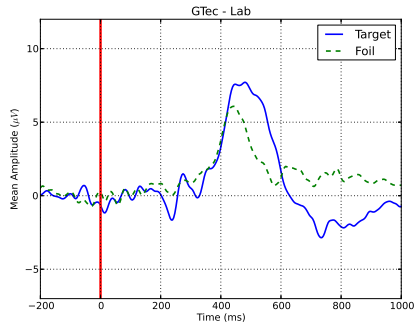

Synchronous BCI

- Synchronous BCI use patterns associated with external stimuli
- P300 speller is an example
- User looks for a specific character in a series or grid of flashing characters

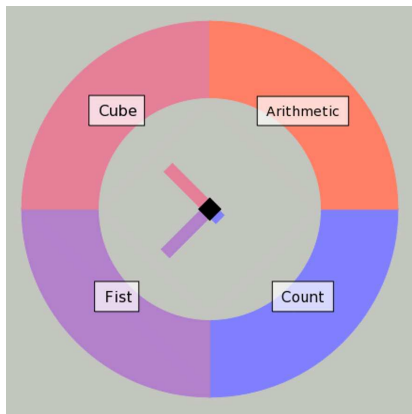

P300 Plot

Asynchronous BCI

- Asynchronous BCI do not require external stimuli
- Mental Tasks is an example
- Imagine left arm moving moves to the left while silently singing a song moves to the right

- Explosion of BCI research in recent years
- Currently testing BCI in real-world conditions and with users that have motor impairments
- Portable, low-cost, easy-to-use EEG systems being developed
- Obama just launched \$100M BRAIN initiative
- Personal prediction: BCI will be commonplace in 10 years

Thanks!
